1 Introduction

MAGE-ML or Microarray Gene Expression Markup Language is a language designed to describe and exchange information about microarray experiments. MAGE-ML is based on XML and can describe microarray designs, microarray experiment setups, gene expression data, and data analysis results.

This package provides the link between MAGE-ML files and BioConductor. It gives the possibility to read in MAGE-ML files that describe cDNA microarray experiments. The functions convert the MAGE-ML files into the customary BioConductor objects (i.e., `marrayLayout`, `marrayInfo` and `marrayRaw` objects or `limma RGList` objects).

Here we give a short introduction to the Microarray and GeneExpression Object Model (MAGE-OM) and how we implemented the extraction of information necessary to make BioConductor objects. For a full description of MAGE-OM, we refer to the Gene Expression Specification: <http://www.omg.org/cgi-bin/doc?formal/03-02-03>.

The main classes of the MAGE object model are `BioSequence`, `QuantitationType`, `ArrayDesign`, `DesignElement`, `Array`, `BioMaterial`, `BioAssay`, `BioAssayData`, `Experiment`, `HigherLevelAnalysis`, `Protocol`, `Description`, `AuditAndSecurity`, `Measurement`, and `BioEvent`.

In MAGE-ML these translate into packages with the same name. The packages needed for building BioConductor objects are `BioAssayData`, `BioAssay`, `BioMaterial`, `BioSequence`, `ArrayDesign`, and `DesignElement`.

The `DesignElement` package contains a mapping of *Features*, which are the actual features present on the array, to *Reporters*, the reporter a feature represents. The `DesignElement` package also provides a mapping from *Reporters* to their corresponding *BioSequence* references. These *BioSequence* objects are characterized by their name and database entries in the `BioSequence` package. The `ArrayDesign` package contains information on the layout of the array. From this package, we can derive the position of each *Feature* on the array in terms of *Zone* (block or grid) and row and column within each *Zone*. The `BioAssayData` package describes the feature references that were assayed and the measured and derived *QuantitationTypes*. The `BioAssay` package describes the different steps in the microarray experiment. The last package used to make BioConductor objects is the `BioMaterial` package and describes how a sample is treated to obtain, for example, labeled samples used for hybridization.

2 Prerequisites

The RMAGEML package depends on SJava(>= 0.68) and a Java VM, e.g. j2resdk1.4.0. Other dependencies are as the Java-MAGEstk API and Java Xerces included in the package itself.

3 Getting started

Installing the package. The package can be installed as a normal R package: download the RMAGEML_2.0.4.tar.gz package and under Unix use the command

```
R CMD INSTALL RMAGEML_2.1.0.tar.gz.
```

The equivalent command for Windows is

```
Rcmd INSTALL RMAGEML_2.1.0.zip.
```

The package automatically loads the Biobase and marrayInput packages from BioConductor and the SJava libraries, so these should be installed as well.

Starting R. Before starting R one should be aware that the RMAGEML package uses SJava and that SJava requires to set the LD_LIBRARY_PATH environment variable before starting R.

Without setting this variable the package won't work

Loading the package. You can load the package into R by typing

```
> library(RMAGEML)
```

4 Import to marray packages

4.1 One step import and creation of an marrayRaw object from MAGE-ML files

In the marray packages of BioConductor the design of an array experiment is typically described by an `marrayLayout` and `marrayInfo` object. The function `importMAGEML` parses all MAGE-ML files present in the directory, which is given as a parameter to the function. From these files it creates an `marrayLayout` object, containing the Layout of one type of microarrays, and an `marrayInfo` object containing the gene names and database entries of the features spotted on the array. The name of the database to which the entries refer, is given in the 'notes' slot of the `Gnames` object. Next the function will extract the raw data values and output a complete *marrayRaw* object as a result.

The function can be tested on the MEXP-14 dataset. This example is available from Array-Express at <http://www.ebi.ac.uk/arrayexpress/>.

If one knows which *DesignElement Dimension*, *QuantitationType Dimension* and *Quantitation Types* are required, the import function can be used as:

```

> datadir <- system.file("MAGEMLdata", package = "RMAGEML")
> raw <- importMAGEML(directory = datadir, package = "marray",
+   arrayID = "A-MEXP-14", DED = "DED:707", QTD = "QTD:707",
+   name.Rf = "QT:F635 Mean", name.Rb = "QT:B635 Median", name.Gf = "QT:F532 Mean",
+   name.Gb = "QT:B532 Median")

```

```

- Java Virtual Machine is running -
parsing MAGEML files
making Layout and Gnames objects

```

```
@maNotes  
character(0)
```

If however you do not know which *DesignElement Dimension*, *QuantitationType Dimension* and *Quantitation Types* to use, you can call the function as follows:

```
> datadir <- system.file("MAGEMLdata", package = "RMAGEML")  
> if (interactive()) {  
+   raw <- importMAGEML(directory = datadir, package = "marray")  
+ }
```

This will generate a few selection panels which allow selection of the appropriate *DesignElement Dimension*, *QuantitationType Dimension* and *Quantitation Types*.

4.2 Creation of a Gnames marrayInfo object

If one just wants to make an marrayInfo object containing the gene names and database identifiers of the spotted features the function getGnames can be used.

```
> data <- system.file("MAGEMLdata", package = "RMAGEML")  
> mageom <- importMAGEOM(directory = data)
```

parsing MAGEML files

```
> getGnames(mageom, arrayID = "A-MEXP-14", DED = "DED:707", package = "marray")
```

An object of class "marrayInfo"

```
@maLabels

955 more rows ...
```

```
@maNotes  
[1] "Identifiers refer to database: DB:embl"
```

Again leaving out the 'DED' parameter will cause selection panels to pop up displaying the available *DesignElement Dimensions*.

4.3 Creation of an marrayLayout object

In the marray packages the information on the array layout is stored in an marrayLayout object which can be created by the getArrayLayout function.

```
> data <- system.file("MAGEMLdata", package = "RMAGEML")
> mageom <- importMAGEOM(directory = data)
```

parsing MAGEML files

```
> getArrayLayout(mageom, arrayID = "A-MEXP-14", DED = "DED:707")
```

```

```
[1] ""
```

4.4 Make an marrayRaw object

The function `makeMarrayRaw` takes a `Gnames` and `Layout` object and parameters corresponding to the *DesignElement Dimension*, *QuantitationType Dimension* and *Quantitation Types* to create an *marrayRaw* object.

```
> data <- system.file("MAGEMLdata", package = "RMAGEML")
> mageom <- importMAGEOM(directory = data)

parsing MAGEML files

> gnames <- getGnames(mageom, arrayID = "A-MEXP-14", DED = "DED:707",
+   package = "marray")
> layout <- getArrayLayout(mageom, arrayID = "A-MEXP-14", DED = "DED:707")
> raw <- makeMarrayRaw(mageOM = mageom, layout = layout, gnames = gnames,
+   directory = data, arrayID = "A-MEXP-14", DED = "DED:707",
+   QTD = "QTD:707", name.Rf = "QT:F635 Mean", name.Rb = "QT:B635 Median",
+   name.Gf = "QT:F532 Mean", name.Gb = "QT:B532 Median")
```

5 Import to limma package

5.1 One step import and creation of a limma RGList object from MAGE-ML files

In the `limma` package of `BioConductor` the raw data is stored in an `RGList` object. The function `importMAGEML` parses all MAGE-ML files present in the directory which is given as a parameter to the function. From these files it creates the `RGList` object, containing the layout, gene names and database entries of the features spotted on the array and the foreground and background intensities for the green and red channels.

The function can be tested on the MEXP-14 dataset. This example is available from Array-Express at <http://www.ebi.ac.uk/arrayexpress/>.

For import to `limma` the same function as `MAGEML` import to `marray` packages can be used, just adapt the name of the package into `limma` as follows:

```

> datadir <- system.file("MAGEMLdata", package = "RMAGEML")
> raw <- importMAGEML(directory = datadir, package = "limma", arrayID = "A-MEXP-14",
+   DED = "DED:707", QTD = "QTD:707", name.Rf = "QT:F635 Mean",
+   name.Rb = "QT:B635 Median", name.Gf = "QT:F532 Mean", name.Gb = "QT:B532 Median")

```

```

955 more rows ...

```

Similarly if one only specifies the ‘directory’ and the ‘package’, selection panels will pop up to select the *DesignElement Dimension*, *QuantitationType Dimension* and *Quantitation Types*.

5.2 Creating the genes dataframe of an RGList object

In limma the gene names, gene identifiers and layout information is stored in a dataframe which can be created by the `getArrayLayoutLimma` function.

```

> data <- system.file("MAGEMLdata", package = "RMAGEML")
> mageom <- importMAGEOM(directory = data)

```

parsing MAGEML files

```

> genes <- getArrayLayoutLimma(mageom, arrayID = "A-MEXP-14", DED = "DED:707")
> print(genes[1:10, ])

```

	Block	Row	Column	ID	Name
1	1	1	1	aj508733	none
2	1	1	2	V00618	none
3	1	1	3	aj291984	none
4	1	1	4	aj306233	none
5	1	1	5	aj310439	none
6	1	1	6	aj409363	none

8	1	1	8	aj306230	none
9	1	1	9	aj310436	none
10	1	1	10	aj291834	none

5.3 Make an RGList object

The function `makeRG` takes a genes dataframe (containing the layout, gene identifiers and gene names), and parameters corresponding to *DesignElement Dimension*, *QuantitationType Dimension* and *Quantitation Types* to create a limma RGList object.

```

> data <- system.file("MAGEMLdata", package = "RMAGEML")
> mageom <- importMAGEOM(directory = data)

```

parsing MAGEML files

```
> genes <- getArrayLayoutLimma(mageom, arrayID = "A-MEXP-14", DED = "DED:707")
> raw <- makeRG(mageOM = mageom, genes = genes, directory = data,
+   arrayID = "A-MEXP-14", DED = "DED:707", QTD = "QTD:707",
+   name.Rf = "QT:F635 Mean", name.Rb = "QT:B635 Median", name.Gf = "QT:F532 Mean",
+   name.Gb = "QT:B532 Median")
```
